

Python Data Structures Cheat Sheet

List

| Package/Method  | Description  | Code Example  |
|-----------------|--|---|
|                 |  | <div>Syntax:<div><div>1. 1</div><div>1. list_name.append(element)</div></div><div>Copied!</div></div>   |
| append()        | The `append()` method is used to add an element to the end of a list.  | <div>Example:<div><div>1. 1</div><div>2. 2</div><div>1. fruits = ["apple", "banana", "orange"]</div><div>2. fruits.append("mango") print(fruits)</div></div><div>Copied!</div></div> <div>Example 1:<div><div>1. 1</div><div>2. 2</div><div>3. 3</div><div>1. my_list = [1, 2, 3, 4, 5]</div><div>2. new_list = my_list.copy() print(new_list)</div><div>3. # Output: [1, 2, 3, 4, 5]</div></div><div>Copied!</div></div> |
| copy()          | The `copy()` method is used to create a shallow copy of a list.  | <div>Example:<div><div>1. 1</div><div>2. 2</div><div>3. 3</div><div>1. my_list = [1, 2, 2, 3, 4, 2, 5, 2]</div><div>2. count = my_list.count(2) print(count)</div><div>3. # Output: 4</div></div><div>Copied!</div></div>   |
| count()         | The `count()` method is used to count the number of occurrences of a specific element in a list in Python.   | <div>Example:<div><div>1. 1</div><div>2. 2</div><div>3. 3</div><div>1. fruits = ["apple", "banana", "orange", "mango"]</div></div><div>Copied!</div></div>  |
| Creating a list | A list is a built-in data type that represents an ordered and mutable collection of elements. Lists are enclosed in square brackets [] and elements are separated by commas.                   | <div>Example:<div><div>1. 1</div><div>1. fruits = ["apple", "banana", "orange", "mango"]</div></div><div>Copied!</div></div>  |
| del             | The `del` statement is used to remove an element from list. `del` statement removes the element at the specified index.  | <div>Example:<div><div>1. 1</div><div>2. 2</div><div>3. 3</div><div>1. my_list = [10, 20, 30, 40, 50]</div><div>2. del my_list[2] # Removes the element at index 2 print(my_list)</div><div>3. # Output: [10, 20, 40, 50]</div></div><div>Copied!</div></div> <div>Syntax:<div><div>1. 1</div><div>1. list_name.extend(iterable)</div></div><div>Copied!</div></div>  |
| extend()        | The `extend()` method is used to add multiple elements to a list. It takes an iterable (such as another list, tuple, or string) and appends each element of the iterable to the original list. | <div>Example:<div><div>1. 1</div><div>2. 2</div><div>3. 3</div><div>4. 4</div><div>1. fruits = ["apple", "banana", "orange"]</div><div>2. more_fruits = ["mango", "grape"]</div><div>3. fruits.extend(more_fruits)</div><div>4. print(fruits)</div></div><div>Copied!</div></div>   |
| Indexing        | Indexing in a list allows you to access individual elements by their position. In Python, indexing starts from 0 for the first element and goes up to `length_of_list - 1`.                    | <div>Example:<div><div>1. 1</div><div>2. 2</div><div>3. 3</div><div>4. 4</div><div>5. 5</div><div>1. my_list = [10, 20, 30, 40, 50]</div><div>2. print(my_list[0])</div><div>3. # Output: 10 (accessing the first element)</div></div><div>Copied!</div></div>  |

```
4. print(my_list[-1])
5. # Output: 50 (accessing the last element using negative indexing)
```

Copied!

Syntax:

```
1. 1
1. list_name.insert(index, element)
```

Copied!

insert()

The `insert()` method is used to insert an element.

Example:

```
1. 1
2. 2
3. 3

1. my_list = [1, 2, 3, 4, 5]
2. my_list.insert(2, 6)
3. print(my_list)
```

Copied!

Example:

```
1. 1
2. 2
3. 3
4. 4

1. my_list = [10, 20, 30, 40, 50]
2. my_list[1] = 25 # Modifying the second element
3. print(my_list)
4. # Output: [10, 25, 30, 40, 50]
```

Modifying a list

You can use indexing to modify or assign new values to specific elements in the list.

Copied!

Example 1:

```
1. 1
2. 2
3. 3
4. 4
5. 5
6. 6
7. 7

1. my_list = [10, 20, 30, 40, 50]
2. removed_element = my_list.pop(2) # Removes and returns the element at index 2
3. print(removed_element)
4. # Output: 30
5.
6. print(my_list)
7. # Output: [10, 20, 40, 50]
```

pop()

`pop()` method is another way to remove an element from a list in Python. It removes and returns the element at the specified index. If you don't provide an index to the `pop()` method, it will remove and return the last element of the list by default

Copied!

Example 2:

```
1. 1
2. 2
3. 3
4. 4
5. 5
6. 6
7. 7

1. my_list = [10, 20, 30, 40, 50]
2. removed_element = my_list.pop() # Removes and returns the last element
3. print(removed_element)
4. # Output: 50
5.
6. print(my_list)
7. # Output: [10, 20, 30, 40]
```

remove()

To remove an element from a list. The `remove()` method removes the first occurrence of the specified value.

Copied!

Example:

```
1. 1
2. 2
3. 3
4. 4

1. my_list = [10, 20, 30, 40, 50]
2. my_list.remove(30) # Removes the element 30
3. print(my_list)
4. # Output: [10, 20, 40, 50]
```

Copied!

Example 1:

```
1. 1
2. 2
3. 3

1. my_list = [1, 2, 3, 4, 5]
2. my_list.reverse() print(my_list)
3. # Output: [5, 4, 3, 2, 1]
```

reverse()

The `reverse()` method is used to reverse the order of elements in a list

Copied!

Syntax:

```
1. 1
1. list_name[start:end:step]
```

Copied!

Example:

```
1. 1
2. 2
3. 3
4. 4
5. 5
6. 6
7. 7
8. 8
9. 9
10. 10
11. 11
12. 12

1. my_list = [1, 2, 3, 4, 5]
2. print(my_list[1:4])
3. # Output: [2, 3, 4] (elements from index 1 to 3)
4.
5. print(my_list[:3])
6. # Output: [1, 2, 3] (elements from the beginning up to index 2)
7.
8. print(my_list[2:])
9. # Output: [3, 4, 5] (elements from index 2 to the end)
10.
11. print(my_list[::2])
12. # Output: [1, 3, 5] (every second element)
```

Copied!

Example 1:

```
1. 1
2. 2
3. 3
4. 4

1. my_list = [5, 2, 8, 1, 9]
2. my_list.sort()
3. print(my_list)
4. # Output: [1, 2, 5, 8, 9]
```

Copied!

Example 2:

```
1. 1
2. 2
3. 3
4. 4

1. my_list = [5, 2, 8, 1, 9]
2. my_list.sort(reverse=True)
3. print(my_list)
4. # Output: [9, 8, 5, 2, 1]
```

Copied!

Slicing

You can use slicing to access a range of elements from a list.

sort()

The `sort()` method is used to sort the elements of a list in ascending order. If you want to sort the list in descending order, you can pass the `reverse=True` argument to the `sort()` method.

Tuple

Package/Method

Description

Code Example

count()

The `count()` method for a tuple is used to count how many times a specified element appears in the tuple.

Syntax:

```
1. 1
1. tuple.count(value)
```

Copied!

Example:

```
1. 1
2. 2
3. 3

1. fruits = ("apple", "banana", "apple", "orange")
2. print(fruits.count("apple")) #Counts the number of times apple is found in tuple.
3. #Output: 2
```

Copied!

index()

The `index()` method in a tuple is used to find the first occurrence of a specified value and returns its position (index). If the value is not found, it raises a `ValueError`.

Syntax:

```
1. 1
1. tuple.index(value)
```

Copied!

Example:

```
1. 1
2. 2
3. 3
```

```
1. fruits = ("apple", "banana", "orange")
2. print(fruits[1]) #Returns the value at which apple is present.
3. #Output: banana
```

Copied!

Syntax:

```
1. 1
```

```
1. sum(tuple)
```

Copied!

Example:

```
1. 1
2. 2
3. 3
```

```
1. numbers = (10, 20, 5, 30)
2. print(sum(numbers))
3. #Output: 65
```

Copied!

Example:

```
1. 1
2. 2
3. 3
4. 4
5. 5
```

```
1. numbers = (10, 20, 5, 30)
2. print(min(numbers))
3. #Output: 5
4. print(max(numbers))
5. #Output: 30
```

Copied!

Syntax:

```
1. 1
```

```
1. len(tuple)
```

Copied!

Example:

```
1. 1
2. 2
3. 3
```

```
1. fruits = ("apple", "banana", "orange")
2. print(len(fruits)) #Returns length of the tuple.
3. #Output: 3
```

Copied!

sum()

The sum() function in Python can be used to calculate the sum of all elements in a tuple, provided that the elements are numeric (integers or floats).

min() and max()

Find the smallest (min()) or largest (max()) element in a tuple.

len()

Get the number of elements in the tuple using len().
